

Layout preservation is the whole point of this tool. A translated page must land its text in the same columns, in the same reading order, as the source page.

The model supplies the reading order. Everything downstream consumes that order rather than the order in which glyphs happen to be drawn.

Where the model is silent, geometry takes over. A fallback sort by column and baseline keeps the pipeline honest when detection misses a block.

Content stream order is not reading order. Engines emit footnotes before body text, and some tools interleave columns line by line.

This fixture exists to make that distinction observable. Two independent parsers report the same page from two different angles.

Nothing here is adjusted to match what the tools produced. The structure was written down first.
